1. Consider the recurrence relation below:

\[ T(n) = \sum_{t=1}^{n-1} T(t)T(t-1) + 1 + T(n-1), \quad T(0) = T(1) = 1, \quad n > 1 \]

a) Write a recursive algorithm (in pseudocode) that computes \( T(n) \) directly as given above. Show that the algorithm performs an exponential number of operations (i.e. solve the above recurrence relation).

b) It is possible to compute \( T(n) \) in a more efficient way, without recalculating the same \( T(i) \) values twice as shown above. Write a more efficient algorithm (in pseudocode) that computes \( T(n) \), which performs \( (n^2) \) operations. Show that it is \( (n^2) \). (Your algorithm must be \( (n^2) \).

c) Write an even more efficient algorithm (in pseudocode) that computes \( T(n) \), which performs \( n \) operations. Show that its is \( (n) \).

2. We know that insertion sort is an efficient algorithm for lists that are nearly sorted. Give a theorem related to this property of insertion sort (i.e. describe this property formally). Then prove the theorem.

3. Consider the graph below:

![Graph](image)

a) Apply depth-first search. Show clearly how the nodes are visited and explain in detail. List the order of node visits.

b) Apply breadth-first search. Show clearly how the nodes are visited and explain in detail. List the order of node visits.

4. We are given the following algorithm:

```plaintext
function Module (L[low:high])
    if (high > low) then
        for i=low+1 to high do
            print (...)
        if (L[i] > L[low]) then
            print (...)
        endif
    endif
    temp = random (low..high)
    call Module (L[low:temp])
    call Module (L[temp:high])
end
```

(continued on next page)
The basic operation is the “print(...)” statements. The algorithm is initially called as “call Module (L[1:n])”. Assume that each element of the array L is a distinct integer between 1 and n. The “random(a..b)” function returns a random number (integer) between integers \(a\) and \(b\) (inclusive), \(a \leq b\). Calculate \(A(n)\) exactly.

Some equations that you may use:

- \(\sum_{i=0}^{n-1} x^i = \frac{x^n - 1}{x - 1}\), for \(x \neq 1\)

- For a binary tree \(T\) with \(L\) leaf nodes, \(LPL(T) \geq L \left\lfloor \log_2 L \right\rfloor + 2 (L - 2 \left\lfloor \log_2 L \right\rfloor)\), where \(LPL(T)\) is the leaf path length of \(T\).

Notes:

- Where pseudocode is required, the syntax of the pseudocode must be strictly followed. No points will be given if the syntax is not followed or any other language (e.g. C) is used.
